ABSTRACT

A number of development assistance programs promote community interaction as a means of building social capital. Yet, despite strong theoretical underpinnings, the role of repeat interactions in sustaining cooperation has proven difficult to identify empirically. We provide the first experimental evidence on the economic returns to social interaction in the context of microfinance. Random variation in the frequency of mandatory meetings across first-time borrower groups generates exogenous and persistent changes in clients' social ties. We show that the resulting increases in social interaction among clients more than a year later are associated with improvements in informal risk-sharing and reductions in default. A second field experiment among a subset of clients provides direct evidence that more frequent interaction increases economic cooperation among clients. Our results indicate that group lending is successful in achieving low rates of default without collateral not only because it harnesses existing social capital, as has been emphasized in the literature, but also because it builds new social capital among participants.

1 Introduction

Social capital, famously defined by Putnam (1993) as “features of social organization, such as trust, norms and networks, that can improve the efficiency of society by facilitating coordinated actions,” is thought to be particularly valuable in low-income countries where formal insurance is largely unavailable and institutions for contract enforcement are weak.¹ Since economic theory suggests that repeated interactions among individuals can help build and maintain social capital (see, for instance, Kreps et al., 1982), encouraging interaction could be an effective tool for development policy. Indeed, numerous development assistance programs have introduced policies designed to promote social contact among community members under the assumption that there are significant economic returns to regular interaction. But can simply inducing people to interact more often actually increase economic cooperation?

While a large body of research finds a positive correlation between social interaction and cooperative outcomes, rigorous empirical evidence on this subject remains limited, largely due to the difficulty of accounting for endogenous social ties (Manski, 1993, 2000). For instance, if more cooperative individuals or societies are characterized by stronger or denser social networks, we cannot assign a causal interpretation either to the positive association between community-level social ties and public goods provision or to the higher levels of cooperation observed among friends as compared to strangers in laboratory public goods games.² In short, without randomly varying social distance, it is difficult to validate the basic model of returns to repeated interaction and even harder to determine whether small changes in social interaction can produce tangible returns.

This paper undertakes precisely this exercise in the context of a development program that

¹Consistent with this idea, Guiso et al. (2004) demonstrate that residents in high social capital regions engage in more sophisticated financial transactions, and Knack and Keefer (1997) show that a country’s level of trust correlates positively with its growth rate.

²The public good provision and community ties literature includes Costa and Kahn (2003); Alesina and Ferrara (2002); DiPasquale and Glaeser (1999); Miguel et al. (2005); Olken (2009), while examples of laboratory games include Glaeser et al. (2000); Carter and Castillo (2004); Do et al. (2009); Karlan (2005); Ligon and Schecter (2008). Another shortcoming in the community ties and public goods literature is the use of survey-generated measures of propensity to cooperate, which are often inconsistent with incentivized trust measures generated by laboratory games (Glaeser et al., 2000).

emphasizes group interaction – microfinance. In the typical “Grameen Bank”-style microfinance program, clients meet weekly in groups to make loan payments. In addition to facilitating debt collection, these meetings encourage regular interaction among members of highly localized communities.³ To evaluate the economic returns to increased social contact that result from participation in group lending, we randomly assigned first-time borrower groups of a microfinance institution (MFI) in India to meet either once per week (weekly groups) or once per month (monthly groups).⁴

We show that mandated differences in meeting frequency over a ten-month period generated persistent differences in individuals’ knowledge of and social contact with group members: Five months into the loan cycle, clients in weekly groups were 90% more likely to have visited other group members in their homes, and more than a year after their loan cycle ended they were 40% more likely to attend social events together and visited one another 19% more often outside of loan meetings. These gains were concentrated among clients who did not know each other well before joining the MFI but had the ability to sustain social contact either through extended family networks or geographic proximity.

Furthermore, reducing social distance had significant economic returns. Clients required to meet more frequently in the experimental loan cycle were 19% more likely to report financial transfers with people outside of their immediate family and 29% more likely to say that they would ask another (former) group member for help in the event of a health emergency. They were also *four* times less likely to default on their subsequent loan (during which all clients met at the same frequency, irrespective of whether they had earlier been in weekly or monthly groups). While in theory it is possible that more frequent repayment directly influenced default via long-run differences in financial discipline, several pieces of evidence indicate that social ties were the central channel of influence. Perhaps most striking, the reduction in default among weekly clients depended heavily

³In an anthropological study of Grameen Bank clients, Laranee (2001) describes the social aspects of weekly activities such as “walking across the village to attend the center meeting, sitting in conversation with a diverse set of women, handling money for the group and receiving personal address.”

⁴In a similar spirit, Humphreys et al. (2009) randomize community development programs and show that they encourage prosocial behavior. However, they are unable to identify the influence of social interactions, per se.

on those group characteristics – fraction of extended family members and close neighbors in the group – that predicted differences in social capital formation. Importantly, these characteristics do not directly influence default.

Not only do these results imply that development programs can readily generate economically valuable social capital, but they provide an alternative explanation for the success of the classic group lending model in achieving low rates of default without the use of collateral. Although joint liability is almost universally emphasized as the key to mitigating default risk in group lending, our results show that improvements in informal risk-sharing arrangements that develop among clients in *individual-liability* lending groups significantly improve repayment rates. Further, recent experimental evidence suggests that joint liability has little impact on default (Karlan and Gine, 2009). Our results also provide a rationale for the current trend among MFIs of maintaining repayment in group meetings despite the transition from group to individual liability contracts (Karlan and Gine, 2009).

To gather direct evidence on economic cooperation among clients and disentangle mechanisms through which repeat interaction improves cooperation, we designed and implemented a second field experiment (roughly sixteen months after the group meeting experiment ended). This lottery experiment provided a unique opportunity to elicit clients' willingness to share risk with group members in a setting that did not trigger subjects' awareness of being participants in an experiment.⁵ Each client entered a separate lottery in which she started with a 1 in 11 chance of winning a Rs. 200 (\$5) promotional coupon. She was offered the opportunity to give out additional lottery tickets to any number of members of her first MFI group, reducing her individual probability of winning but increasing the probability that someone from the group would win. Since ticket-giving increases her expected payoff if and only if group members could be trusted to share their winnings an individual's willingness to give tickets captures the "resource potential" of her MFI network.

⁵Subjects' awareness of being scrutinized has been shown to influence laboratory measures of pro-social behavior. In a recent overview of this literature, Levitt and List (2009) argue that individuals' pro-social behavior in framed or artificial experiments is likely to depend on the nature and degree of others' scrutiny, the context in which a decision is embedded and the selection of participants, which significantly limits the generalizability of these results.

To distinguish insurance motivations for sharing from unconditional altruism, we varied the form of lottery prize, randomly assigning each client to a lottery in which the prize was either one Rs. 200 voucher or four Rs. 50 vouchers. Assuming the more easily divisible prize is perceived as more conducive to sharing by the winner, a client will be more likely to give tickets to group members when the prize is divisible if she is motivated at least in part by risk-sharing considerations but no more likely if she is motivated only by selfless altruism.⁶ Consistent with this, we find that, relative to a monthly client, a client who had been in a weekly group was 67% more likely to enter a group member into the lottery when the prize was divisible but no more likely when it was not. Further, in line with our earlier results we find that increased ticket-giving by weekly clients is driven by increased giving to close neighbors and extended family.

Why do more frequent meetings facilitate risk-sharing? We exploit a unique feature of our experimental setting to evaluate the importance of learning about fellow group members types (level of impatience, trustworthiness, etc.), which implies only short-term benefits of more frequent interaction, versus the possibility that regular interaction indefinitely improved risk-sharing capacity by increasing clients' effective discount factors or ability to implement punishment and reward schemes that mitigate opportunistic behavior. At the time of the lottery, a subset of participants were on a subsequent loan cycle in which their group had been re-randomized into weekly or monthly repayment schedules. This provides experimental variation in the frequency of mandatory interactions between group members at two points: once when they are new to each other and once when they have been interacting regularly for almost two years. Clients randomly assigned to meet frequently in both loan cycles give significantly more tickets than clients required to interact at a high frequency only in the beginning. We interpret this as evidence that, in addition to any learning effects that hasten the formation of reciprocal arrangements, higher meeting frequency also helps

⁶Similar variations of dictator or trust games have been used to parse out motives for giving in laboratory experiments. See for instance Ligon and Schecter (2008); Do et al. (2009); Carter and Castillo (2003). Perhaps closest to our approach is Gneezy et al. (2000), who use a sequence of trust games with varying constraints on the amount that can be repaid in the second round to show that individuals contribute more when large repayments are feasible.

sustain cooperation by reducing the costs or increasing the benefits of coordinating actions.

Our findings compliment existing work on microfinance, which has identified a role for social connections in reducing default risk (Besley and Coate, 1995; Ghatak and Guinnane, 1999; Karlan, 2005).⁷ Our contributions are to generate and use random variation in social ties to establish a *causal* effect of social interaction on cooperation that we cannot safely conclude from previous studies (given the possibility of selection into social networks), and, in doing so, to demonstrate that small changes in program design (here, the structure of the loan contract) can have a significant effect on social capital. With respect to microfinance, our findings illustrate that the most popular form of group lending not only harnesses social capital through joint liability contracts but actually builds social capital among group members by encouraging regular social contact.

The rest of this paper is structured as follows: Section 2 describes the study setting and experimental design. Section 3 documents the implications of meeting frequency for clients' social and financial behavior. Section 4 uses our second field experiment to disentangle channels through which increases in social interaction increased economic cooperation, and Section 5 concludes.

2 Setting and Experimental Design

Our partner MFI, Village Welfare Society (VWS), started operations in the Indian state of West Bengal in 1982. At the start of our field experiments, it had roughly 6.75 million dollars in outstanding loans to over 56,000 female clients. According to the baseline survey, over 70% of households in our sample owned a micro-enterprise, 30% report significant health shocks in the twelve months prior to taking out a loan, and less than 40% had a savings account or formal insurance, suggesting potentially significant returns to informal risk-sharing among group members.

Like most MFIs, VWS loan groups typically consist of clients from a single neighborhood, which implies that members live in close proximity and are acquainted prior to joining. However,

⁷For instance, MFI clients in Peru who are more trustworthy in a trust game are less likely to default, and group-level default is lower in groups where clients have stronger social connections (Karlan, 2005, 2007).

while 67% of group members in our sample knew one another at group formation, most described their relationship with other group members as neighbors (51%), acquaintances (6%), or strangers (27%), rather than friends (7%) or family (9%).

The basic loan group works as follows: After clients are screened and groups approved by loan officers, members choose a group leader in whose home the loan officer will conduct weekly repayment meetings for the duration of the loan cycle. The first two meetings are for group nurturing and training, and loan repayment starts in the third week. During each meeting clients take an oath promising to make regular repayment, after which the loan officer collects payment from each member individually and marks passbooks.⁸ Loan cycles last for forty four weeks and all clients must attend meetings for at least twenty weeks, after which point they may repay the remaining balance in a single installment. In our sample the median weekly group met thirty seven times during a single loan cycle and the average meeting length was twenty-five minutes (excluding waiting time).

For the experiment, between April and September 2006 we recruited one hundred new ten-member borrower groups of first-time clients from neighborhoods in the catchment areas of three VWS branches.⁹ At the time of recruitment, clients were told that repayment schedules would be determined by lottery. Before loan disbursement, we randomly assigned thirty groups to the standard weekly repayment schedule and seventy groups to a monthly repayment schedule.¹⁰ Each client received a Rs. 4000 (\$100) loan, a reasonably large amount given that the average client had assets worth \$250 at baseline. Clients assigned to the weekly schedule were required to repay their loans through 44 weekly installments of Rs. 100 starting two weeks after loan disbursement, and those assigned to the monthly schedule in eleven Rs. 400 installments starting one month after loan

⁸A client's repayment behavior is, thus, observable to other group members, although, in practice most clients socialize while awaiting their turn. While a client can repay at a branch this occurred very rarely. However, once a majority of clients in a group have repaid their loan, VWS asks remaining clients to repay at the branch office.

⁹Loan officers aimed to form ten-member groups. In practice, group size ranged between eight and thirteen members, with 77% of the groups consisting of ten members.

¹⁰We originally intended to have two monthly repayment treatment arms: One that met weekly and one that met monthly. In practice, weekly meetings among clients required to repay monthly broke down almost immediately, and clients ended up meeting on a monthly basis for most of their loan cycle. On average the weekly-monthly and monthly-monthly groups ended up meeting 10.13 and 10 times.

disbursal. No client dropped out after her repayment schedule was announced.

Between group formation and loan disbursement, we administered a baseline survey to 1016 of the 1026 clients. Table 1 and Appendix Table 1 provide a randomization check based on these data. On average, monthly and weekly clients look similar at baseline across a wide range of observable characteristics. No baseline characteristics out of 30 are significantly different at a 5% level, and only two differences are statistically significant at the 10% level: whether a client is Muslim and the number of years she has lived in her neighborhood. While monthly clients have been in their neighborhoods for slightly longer, the difference is relatively small and is not associated with differences in degree of social ties. For instance, they were no more likely to describe another group member as family or friend (Table 1, Panel B). We have also verified that the results are robust to excluding groups with Muslim clients. However, because of these differences, throughout we report regressions with the controls listed in Table 1 and discuss any cases in which our results are sensitive to the inclusion of controls.

3 Effect of Meeting Frequency on Client Behavior

To gauge the effect of meeting frequency on social capital formation, our study tracks clients for two and a half loan cycles (roughly 100 weeks) beginning in April 2006. Appendix Figure 1 provides a detailed timeline.

3.1 Social Capital Effects

We first measure short-run changes in group members' social contact outside of repayment meetings during the course of the experiment. To capture this, at the end of each meeting loan officers asked clients four questions about their knowledge of and interactions outside of meetings with other group members. Since data were collected in a relatively public setting, to maintain a degree of anonymity clients were asked to aggregate their interactions across group members.

To capture the breadth of client interactions outside of meetings, each client was asked whether all group members had visited her at home and whether she had visited all other group members in their homes.¹¹ For both outcomes, we construct an indicator that equals one if the client responded in the affirmative at any group meeting. To capture clients' knowledge of group members, each client was asked if she knew the names of her group members' husbands and children and whether any of her group members had relatives visit in the last thirty days. For the first measure, we again construct an indicator that equals one if the client responded in the affirmative at any group meeting, and for the second we average across all responses for a client. To avoid inferences based on selected outcomes, we report effects for a "social contact index" which averages across these four outcomes (Kling et al., 2007).¹² Since clients often repay early but never before the sixth month, we restrict the analysis to data from the first five months of the loan cycle.¹³ To balance observations across weekly and monthly clients, we randomly choose one meeting per month for weekly clients.

Figure 1 shows that the fraction of clients who had visited all group members in their homes rose sharply in the first month and then increased gradually over the next five months to nearly 45%, and the fraction of clients who knew whether their group members had been visited by relatives increased steadily from 0% to 7%. We observe similar patterns for fraction of clients visited by all group members and knowledge of the names of family members of other group clients (unreported). These patterns are consistent with a "dose response" to mandatory meetings, in which case weekly groups should end up with higher levels of social contact. To test this, we aggregate social contact data to the group level – since client responses may have been influenced by being asked in a group setting – and estimate for group g :

$$y_g = \beta_1 W_g + X_g \gamma_1 + \alpha_g + \epsilon_g \quad (1)$$

¹¹Repayment meetings always occur at the group leader's house.

¹²The index is the equally weighted average of the four variables, with each variable normalized by subtracting the mean for monthly clients and dividing by the standard deviation for these clients.

¹³Due to delays in implementing the group meeting survey, 1.9% of clients (20 clients) lack eight weeks of data, 4.8% (49 clients) lack data for 6 weeks, and 7.8% (80 clients) lack four weeks of data.

where y_g is the social capital index, W_g is an indicator for weekly group, α_g is a loan officer fixed effect, and X_g is the set of group-level controls in Table 1. Regression results, presented in column (1) of Table 2, indicate that moving from monthly to weekly repayment leads to a four standard deviation increase in social contact outside of meetings.¹⁴

To examine whether changes in social contact persisted beyond the experiment and measure individual social interactions in a more controlled setting, we visited a random sample of 432 clients an average of 16 months after they had repaid their loan and collected survey data on the client's perceptions of the trustworthiness of her previous (first loan cycle) group members and her current contact with these members.¹⁵ For consistency with short-run data collected during loan meetings, our first long-run contact measure is the number of times over the last thirty days the client had visited with a previous group member in either person's home. The next two outcomes measure the strength of social contact – whether the client still talks to the group member about family and whether they celebrated the main Bengali festival (Durga Puja) together during the previous year.

Since we have roughly nine observations per client (all other group members), our analysis sample contains 4018 pairwise observations. In order to avoid double-counting, in cases in which we interviewed both members of a pair, we randomly drop one observation when the outcome is social contact (which cannot vary, in the absence of measurement error, within a pair) and keep all observations for outcomes that can differ within a pair. For member i matched with group member m in group g we estimate

$$y_{gmi} = \beta_1 W_g + X_g \gamma_1 + X_i \gamma_2 + \delta_1 D_i + \delta_2 l_i + \alpha_g + \epsilon_{gmi} \quad (2)$$

where overlapping variables are defined as in equation (1), D_i controls for number of days between loan disbursement and survey, and l_i controls for being the group leader. Additional controls, listed

¹⁴In Appendix Table 2, we report the differences for each of the index components (for ease of interpretation we consider the non-normalized group outcomes). In each case, the magnitude of the effect is strikingly large. All results are robust to excluding controls.

¹⁵The client also provided information on her relationship with each group member prior to joining VWS.

in Table 1, are defined at the group- and individual- level (X_g and X_i respectively). Standard errors are clustered by group.

According to the estimates in column (2) of Table 2, more than a year after graduating from their first loan cycle, clients who met weekly remain significantly more likely to interact than their monthly counterparts: Moving from a monthly to a weekly schedule leads to a 0.11 standard deviation increase in long-run social contact between clients. The effect is similar in magnitude but statistically insignificant without controls. Furthermore, all of the individual index components indicate greater social contact among weekly clients and two out of three are statistically significant (Appendix Table 2). In sum, higher levels of friendship among weekly clients persisted long after mandatory meetings ended.

Next, we examine how long-run changes in social contact varied across five categories of baseline social distance: (i) immediate family members and friends; (ii) relatives more than once removed (distant relatives); (iii) neighbors living within a block (close neighbors); (iv) neighbors living more than a block away (far neighbors); and (v) strangers.¹⁶ Column (3) reveals that increases in long-run social contact that accrue to weekly groups are concentrated among client pairs who are distant relatives and close neighbors. Reassuringly, we do not observe a change in social contact among immediate relatives (the omitted group), and not surprisingly, we also observe no significant change among clients with few means of sustaining a social connection outside of group meetings (those who were unknown prior to joining VWS or distant neighbors). These results are robust to the exclusion of controls.

Looking directly at the component of the index that measures repeat interaction – number of times the pair visited each other at home in the last thirty days – we observe that the average weekly client pair meets 19% more often than their monthly counterpart, but the estimate is very noisy (column (4)). However, when weekly is interacted with categories of initial social distance, we observe large and significant increases in meeting frequency where changes in social ties are

¹⁶Distances were measured using GPS coordinates collected at baseline. We define a city block as living within a 50-meter radius, which is half of the distance used to define city blocks in developed countries.

most heavily concentrated - among distant family and close neighbors. Among weekly clients, close neighbors see each other just as often as friends and family members once removed while in monthly groups they see each other 27% less often.

The last two columns consider trust-based measures of social capital. The outcome in column (6) is a client's perception of her average group member's trustworthiness.¹⁷ More than a year after repaying the loan, those who were on a weekly schedule rank average group member trustworthiness 0.27 points higher (on a 1-5 scale) and the difference is statistically significant with or without controls.¹⁸ In column (7), the outcome variable is the client's response to a hypothetical question on whether she believes that a particular group member would help her in the event of illness. Weekly clients are six percentage points more likely to report that a group member would provide assistance in such an emergency (29%), which is statistically significant with but not without controls.

3.2 Returns to Social Capital

According to the previous section, forcing people to meet more often for 6-10 months leads to persistent increases in social ties. But do these social ties yield economic returns or simply change patterns of friendship? Survey responses to a hypothetical scenario suggest that weekly clients are also more willing to provide informal insurance to fellow group members (Table 2, column (7)), but do informal risk-sharing arrangements develop in practice?

To test whether weekly meetings are associated with improvements in informal insurance, we consider two measures of vulnerability to shocks: financial transfers between individuals other than immediate family and loan default. At the end of the first loan cycle clients were administered a survey that asked about the number and amount of transfers to and from individuals of fourteen

¹⁷Our regression specification is the individual level equivalent of equation (1).

¹⁸The client was described the following scenario: "Imagine a person walking down the street sees someone in front of him/her drop their wallet. Upon inspection, she finds that the wallet contains Rs 200 and the owner's name and phone number. The finder must decide whether to keep it or return it to its owner." She was asked to rank the likelihood that the finder would return the wallet if she was her average group member on a 1-5 scale described as follows: "1-Would not return the money. 2- Unless someone knows she has got the wallet, would not return it. 3-As likely to return as not. 4- Will return, but might take up to a week. 5- Will return immediately."

different relationship categories over the past year. Figure 2 shows the average transfers given by a client by type of relationship. Overall, weekly clients give more transfers to all categories of individuals except non-relatives who are neither friends nor neighbors, a category that is unlikely to include members of a client's loan group. Among client pairs in the two categories where gains in social ties are concentrated - friends (at endline), neighbors and other relatives - , total transfers are 28% higher among weekly clients. Since the majority of clients report no transfers, for regression estimates we consider the binary outcome of whether the client reports any transfers to or from individuals inside or outside of her immediate family rather than amount of transfer.

To measure default, we use VWS transactions data to track client repayment behavior during both the experimental and the subsequent loan cycle. At the end of our loan experiment, 69% of clients took out a second loan with VWS, and the rate did not differ across monthly and weekly clients. On average, the second loan was 35% larger than the first, and all clients repaid on a fortnightly schedule.¹⁹ We consider a client in default on either loan if she failed to repay in full 44 weeks after the loan was due (roughly the length of an additional loan cycle).²⁰

For both outcomes, we estimate OLS regressions of the form:

$$y_{gi} = \beta_1 W_g + X_g \gamma_1 + X_i \gamma_2 + \alpha_g + \epsilon_{gi} \quad (3)$$

where variables and indices are defined as in Equation (2).

The results are presented in Table 3. Column (1) reveals that weekly clients are 19% more likely to report transfers outside the family at the end of the experiment, and the difference is significant at the 10% level. Furthermore, these transfers do not appear to displace transfers within the immediate family or to individuals outside of the neighborhood (column (2)), suggesting a net gain in informal insurance.

Since improvements in risk-sharing have implications for default rates, the next three columns

¹⁹Clients in the second loan cycle were subject to experimental variation in the timing of first repayment, but it was independent of their first loan repayment schedule. See Appendix 7.3 for details.

²⁰Results are very similar if we vary the time period over which default is defined.

look at default in the experimental and subsequent loan cycles. Column (3) shows that frequent meetings are *not* associated with lower default in the first loan cycle. An important caveat is that default is extremely low for first-time borrowers (1.8%), presumably due to the fact that, following standard MFI practice, first loan sizes are below client demand for credit and “carrying capacity.” However, once clients have graduated to larger loans, differences in default emerge despite the fact that all clients have by that point converged to the same meeting frequency (fortnightly). Clients assigned to monthly meetings for their first loan are four times more likely to default on their *second* loan relative to clients assigned to weekly meetings for their first loan, and the difference is statistically significant (column (4)).

Next we examine whether default reductions were concentrated among weekly clients most likely to experience gains in social contact. The point estimates in column (5) indicate that this is the case: There is a large and significant effect of weekly meeting on default only among clients with a sufficient number of close neighbors and/or distant relatives in their group. This is reassuring since it provides evidence that default patterns are not driven by the direct effect of meeting frequency. That is, if the main channel of influence were the meeting itself (e.g. the oath, loan officer indoctrination, ability to repay in small installments), we would not expect default rates to differ systematically by features of group composition that do not directly predict default. We interpret the findings in Table 3 as *prima facie* evidence that meeting more frequently helped clients build stronger social ties and then leverage these social ties to deal with shocks (and maintain repayment).

The findings in Table 3 compliment Table 2 results in two ways: First, changes in social contact that occur as a result of meeting regularly in loan groups have real economic returns and therefore correspond to economically meaningful changes in social capital. Second, these measurable returns to new relationships do not appear to be crowding out equally valuable relationships with people outside of the loan group, as evidenced by lower overall vulnerability to shocks. Hence, we can conclude that our intervention caused a net gain in social capital.

4 The Lottery: Disentangling Channels of Influence

A shortcoming of our survey data is that we cannot directly observe instances of risk-sharing between group members, only aggregate outcomes (total transfers and default). Hence, to gather direct evidence on the effect of group meetings on economic cooperation and evaluate the potential channels of influence, we conducted a field experiment in the form of a promotional lottery more than a year after clients completed their first loan cycle (average final repayment and survey dates were April 2007 and July 2008, respectively). Our experiment, a variant of laboratory dictator and trust games (Forsythe et al., 1994; Berg et al., 1995), was designed to elicit willingness to form risk-sharing arrangements in a field setting.²¹

4.1 Design

We drew a random sample of 450 clients and successfully contacted 432 spread across 98 groups, yielding a final sample of 129 weekly and 321 monthly clients (see Appendix for details). Table 1 provides a randomization check using group-level (Panel A) and client-level (Panel B) variables. Column (4) shows that the lottery sample is representative of the experimental population, and columns (5) and (6) examine the balance of voucher randomization (described below) on multiple characteristics. As before, the two characteristics which are unbalanced remain fraction Muslim and years in the neighborhood. The weekly clients in the Rs. 200 voucher randomization also have slightly fewer closer neighbors (compared to monthly counterparts). We continue to report regressions with the full set of controls and report any instances where the results vary with controls.

The protocol was as follows: Surveyors approached each selected client in her house and invited her to enter a promotional lottery for the new VWS retail store.²² The lottery prize was gift vouchers worth Rs. 200 (\$5) redeemable at the store (see Appendix for the surveyor script). Aside

²¹In the dictator game, the experimenter asks an individual (sender) to divide a fixed amount of money between herself and another individual (receiver). In the trust game, the money transfer is typically tripled by the experimenter and the receiver is explicitly asked how much she wishes to send back to the sender.

²²Importantly, the lottery protocol was conducted before the Table 4 survey data were collected.

from banking, VWS undertakes many community interventions and conducts regular promotional activities in an effort to attract and retain clients. For this reason, our intervention is likely to seem natural in this setting.

The client was informed that, in addition to her, the lottery included ten clients from different VWS branches, which she was therefore unlikely to know. If she agreed to enter the draw (all clients agreed), then she was given the opportunity to enter any number of other members from her first VWS group into the same draw. Any group member she entered into the lottery would receive a lottery ticket delivered to her house and be told whom it was from. She was told that the other ten participants would not be given the opportunity to add individuals to the lottery.

To clarify how ticket-giving influenced her odds of winning, the client was shown detailed payoff matrices (see Figure 3). Enumerators explained that she could potentially increase the number of lottery participants from 11 to as many as 20, thereby increasing the fraction of group members in the draw from 9% to up to 50% while decreasing her individual probability of winning from 9% to as low as 5%.

A client belonging to a ten-member group made nine pair-wise choices. Similar to trust and dictator games, a member who received a ticket was not required to share her winnings. In the absence of any sharing arrangements, the Nash outcome is to not give any tickets. Ticket-giving increases a client's expected payoff only if she trusts the recipient to share lottery earnings.

While alternative sharing arrangements are feasible, for expositional ease, we consider the simple case of pairwise cooperation when the client (or sender) gives a single group member (receiver) a ticket. For this pair, expected joint earnings increase since their joint chances of winning the lottery rise from 9% to 17%. There are mutual gains from cooperation (if the receiver shares half of her earnings, the sender's expected lottery earnings rise from Rs.18 to 25 and the receiver's expected earnings rise from Rs.0 to 8.3), but costs to the sender if the receiver does not plan to share earnings with her (in which case the sender's expected lottery earnings fall since her individual probability of winning the lottery declines from 9% to 8% as the pool of lottery entrants rises to twelve).

Appendix Figure 2 illustrates how ticket-giving changes a client's expected payoff. The top

line shows her expected payoff when the receiver shares half her winnings with the client, and the bottom line shows the reduction in her payoff if no receiver shares. The figure also illustrates a key difference between our lottery and the trust game: Pairwise returns in the lottery depend on total tickets given. If the sender trusts all other group members equally then she would give equally to all group members. However, if trust of group members varies, then recognition of this externality will further constrain ticket-giving to less trusted group members.²³

Finally, to isolate cooperative from purely altruistic motives for giving tickets, our experiment varied the divisibility of the lottery prize. For a randomly chosen half of participants, the lottery prize was one Rs. 200 voucher, while for the other half it consisted of four Rs. 50 vouchers. Appendix Figure 3 provides pictures of these vouchers. A voucher could only be redeemed by one client and all vouchers expired within two weeks.

4.2 Predictions

Stronger social ties should positively impact pro-social behavior. Hence,

Prediction 1 *Higher meeting frequency in the first loan cycle will increase ticket-giving.*

Ticket-giving could increase for two broad reasons. First, in a setting in which clients lack access to explicit binding contracts, an increase in the frequency of interaction can enable a pair of clients to devise and implement punishment and reward strategies that sustain reciprocal economic arrangements, including informal insurance schemes (Karlan et al., 2009; Besley and Coate, 1995; Ambrus et al., 2010). Alternatively, more frequent meetings may increase a client's unconditional altruism towards other group members. To distinguish between these two possibilities, we exploit random variation in the divisibility of the lottery prize and make use of baseline heterogeneity across clients in self-reported financial autonomy to make transfers, both of which should influence the ticket-giver's expectations of reciprocal ties. Neither a more divisible lottery prize nor the receiver's ability to make transfers should induce greater ticket-giving unless the sender cares about the ease

²³It is also the case that, in our game, sender's action and payoffs are stochastically related which also differentiates it from the classic trust game.

of reciprocal transfers. Hence,

Prediction 2 *If the primary channel is (unconditional) altruism, then the incidence of ticket-giving will be independent of perceived ability of the receiver to reciprocate.*

Meeting more frequently during the initial loan cycle can encourage reciprocal arrangements between client pairs in multiple ways. Under certain circumstances more frequent meeting may increase the scope of cooperation by improving clients' ability to monitor other members' actions. Consider the case in which members can influence their income through hidden actions. If different actions by members at time t imply different initial conditions for the income generation process between t and $t + \Delta$ (where Δ is the time period between two meetings), observing income (at meetings) provides a public signal of a member's action (Costa, 2007).²⁴ Hence, higher frequency of meeting can improve monitoring in the sense of increased precision of the public signals.

Meeting more often can also change individuals' effective discount factor. In a repeated game framework, the suitable use of punishment strategies (e.g. grim trigger strategy) can sustain cooperation among sufficiently patient individuals (Fudenberg and Maskin, 1986); for application to informal insurance see Coate and Ravallion (1993)). Here, a higher frequency of meeting can be modeled as reducing the period length between each repetition of the stage game. With perfect monitoring, this is equivalent to raising the effective discount factor of pair members, which makes it more likely that relatively impatient members can sustain cooperation. The positive returns to mandating more frequent meeting will persist as long as meetings continue to reduce the expected duration between repeat interactions. Hence,

Prediction 3 *Increases in ticket-giving among weekly clients will be concentrated among those who are relatively impatient only if the channel is improved reciprocal sharing arrangements.*

An alternative channel through which repeat interaction at the start of a relationship can facilitate reciprocity is by hastening learning about other group members' ability and willingness to cooperate. Such a learning-based story by itself would imply that returns to mandating frequent

²⁴If actions do not differentiate initial conditions, higher frequency signals may not increase the reliability of information extracted from public signals (D. Abreu and Pearce, 1991; Fudenberg and Levine, 2009).

interaction will diminish over time. To evaluate the importance of learning about types in explaining our results, we exploit the following fact: At the time of our lottery, a subset of clients were on a subsequent loan cycle in which they had been re-randomized onto weekly or monthly schedules. This allows us to test the following prediction:

Prediction 4 *If the primary channel is learning, the effect of more frequent interaction will be significantly lower in future loan cycles.*

4.3 Results

4.3.1 Determinants of Ticket-Giving

Our primary outcome of interest is ticket-giving. For each member of a client's first loan group, we recorded whether the participant entered her into the lottery. In total, 57% of participants gave at least one ticket, which is very similar to individual propensity to give in dictator games (Levitt and List, 2009). To see how individual and pairwise characteristics, including meeting frequency, predict ticket-giving by lottery client i in group g , we pool our sample of weekly and monthly lottery clients and estimate:

$$y_{gmi} = X_i\gamma_1 + X_{im}\gamma_2 + X_m\gamma_3 + \phi_g + \alpha_g + \epsilon_{gmi} \quad (4)$$

where y_{gmi} denotes whether client i gave group-member m a ticket. We are interested in the influence of sender characteristics (X_i), receiver characteristics (X_m), and pairwise characteristics (X_{im}). All regressions include loan officer (α_g) and month of group formation (ϕ_g) fixed effects.

The basic patterns in the data are broadly consistent with findings in the trust and dictator game literatures. Column (1) of Table 4 shows that educated clients are more likely to give and receive tickets. Richer respondents, those who state in baseline that they can make transfers outside of their household (financial control), and the group leader receive more tickets. In contrast, respondents who participate in community and political events are more likely to give but not receive tickets. Finally, ticket-giving is higher when both members are impatient.²⁵ In column (2), we

²⁵We measure baseline impatience with a series of questions where the client chooses between Rs. 200 today versus

distinguish between pairs on the basis of initial social distance. As expected, ticket-giving falls with social distance: Neighbors are much less likely to receive a ticket than friends or family members, and group members that were previously unknown rarely receive tickets (the unconstrained means across these three categories are roughly 25%, 53%, and 11%).

4.3.2 Initial Meeting Frequency and Ticket-Giving

Next we examine whether ticket-giving behavior varied systematically with initial meeting frequency. Figure 4 shows the distribution of tickets for weekly and monthly clients (in percentage terms to account for group size differences). After zero tickets, the fraction of group members that receives tickets declines gradually and then levels out after 60%. Weekly clients are substantially less likely to give no tickets and more likely to give tickets to more than half of their group.

In Table 5 we provide regression results of the form given by equation (2). Columns (1) - (4) present results for clients offered the divisible lottery prize while columns (5) - (8) show results for clients randomized to the lottery with the less divisible prize. A comparison of columns (1) and (5) shows that, relative to her monthly counterpart, a client in a weekly group is significantly more likely to give a ticket to a group member if and only if the lottery prize is divisible. Weekly clients in the divisible randomization are 67% more likely to give tickets than monthly clients, whereas there is almost no difference between monthly and weekly clients when the prize comes in the form of one large voucher.²⁶ Figure 5 shows four loan group networks that highlight the empirical ticket-giving patterns found in the data (the full set of ticket-giving networks are shown in Appendix Figure 4). Weekly clients' higher propensity to give tickets is reflected in the higher relative connectedness of the weekly networks in the divisible (i.e., circular nodes) but not the indivisible (i.e., square nodes) gift voucher randomization. Significantly higher ticket-giving among weekly clients when the lottery prize is easily divisible suggests that more frequent meetings increased ticket-giving by increasing

between Rs. 210 and Rs. 250 in a month.

²⁶In the pooled sample, the estimate of the coefficient on the interaction between weekly and divisible prize is similar in magnitude but statistically insignificant, with a t-statistic of 1.54.

expectations of reciprocity.²⁷ If frequent meetings had only increased *unconditional* altruism, then ticket-giving would be independent of voucher divisibility.

In columns (2) and (6), we examine whether ticket-giving is sensitive to a client's subjective discount rate. If expectations of reciprocal transfers sustain ticket-giving, ticket-giving should only be observed among sufficiently patient client pairs, and more frequent interaction can potentially allow relatively impatient pairs to sustain cooperation. To investigate this, we create a dummy that equals one if both members of a pair prefer Rs. 200 today to Rs. 250 in a month. In column (2), we observe that weekly meetings make it more likely that impatient pairs engage in ticket-giving: the coefficient estimate on the interaction between weekly and impatience is large and statistically significant. Again, this relationship is only present for clients assigned to the divisible lottery prize, consistent with the fact that ticket-giving is no greater for weekly clients when the prize is less divisible. This pattern suggests that risk-sharing concerns underlie increased ticket-giving among weekly clients, since impatience should not influence unconditionally altruistic behavior.²⁸

In columns (3) and (7), we examine whether ticket giving is sensitive to the level of financial control exercised by the receiver. In total, 89% of clients responded affirmatively to the baseline survey question, "If a close relative like your parents or siblings fell sick and needed money, would you be able to lend money to that relative, if you had the extra money?" If risk-sharing motivates the higher level of ticket-giving observed in the divisible voucher case, and assuming that this characteristic is to some extent observable to other members, we would expect a client to avoid giving tickets to those who are unable to reciprocate. In line with this, we see that marginal ticket-giving is concentrated among the set of potential receivers who report that they have the financial independence to make transfers outside of the household.

Finally, in columns (4) and (8), we examine whether the weekly effect differs by initial social

²⁷ Anecdotal evidence from conversations with clients also suggested that they believed multiple vouchers increased the likelihood that those they gave tickets to would share any future winnings.

²⁸ We hypothesize that the net positive effect of pairwise impatience on ticket giving among weekly clients results from impatient clients likely having smaller social networks before the start of the loan cycle, and consequently having higher demand for risk-sharing arrangements.

distance. The coefficient estimates on the interaction terms indicate that increased ticket-giving by weekly clients is driven by increased giving to close neighbors and distant family. The fact that increased ticket-giving by weekly clients is concentrated among the categories of pairs in which we also observe a significant effect on social contact (Table 2) is consistent with our interpretation that higher long-run social contact increased propensity to form risk-sharing arrangements. The fact that moving from a monthly to a weekly repayment schedule did not influence ticket-giving to close family and friends provides an important placebo check: For immediate family members or old friends, repayment schedules should not influence learning or monitoring since these pairs presumably know each other well and see each other often outside of meetings. Also consistent with this is the fact that ticket-giving is no higher among weekly relative to monthly clients who report that they never see one another: Both sets of clients give tickets to roughly 15% of group members whom they have not seen at all in the past 30 days.²⁹

The fact that we observe no difference among monthly clients' ticket-giving across the two voucher categories, along with the fact that for monthly clients ticket-giving is independent of impatience and ability to reciprocate, suggests that either ticket-giving among these members is not primarily motivated by reciprocity, or that only marginal risk-sharing arrangements are sensitive to small barriers to trust such as prize divisibility. A few empirical patterns support this interpretation: First, 61% of tickets given by monthly clients do not appear to be reciprocal arrangements, based on the fact that they are given either to individuals they have not seen in the last 30 days at the time of the lottery or from whom they claim they would not ask for help in case of emergency, or to immediate family members. Second, survey data indicate that monthly meetings did not lead to long-run changes in social capital, indicating an absence of relatively new informal risk-sharing arrangements among monthly clients. For instance, monthly group members are no more likely to report giving or receiving transfers to individuals outside of the immediate family between baseline and follow-up (unreported).

To examine whether ticket-giving was associated with reciprocal transfers, six months after

²⁹Authors' tabulations.

the lottery, we surveyed 39 of the 47 clients who received a ticket from a group member and won that lottery.³⁰ Although we do not observe explicit voucher-sharing (the winners always redeemed their vouchers as opposed to giving them away), nearly all clients (85%) remembered who gave them their ticket, and a quarter reported greater willingness to share post-lottery. We also observe a significant difference across weekly and monthly clients, consistent with higher rates of risk-sharing relative to altruism among ticket-givers – 7/23 (30.4%) of weekly clients but only 1/16 (6.3%) of monthly clients report such willingness.³¹

4.3.3 Hastening versus Sustaining Cooperation

As explained in Section 4.2, more frequent interaction may help sustain cooperative arrangements indefinitely, or it may simply hasten the formation of cooperative arrangements through more rapid learning about client types. One basic piece of evidence against the learning story is that, at the time of the lottery, the majority (69%) of clients have been in loan groups together for almost two years, by which point types should arguably be revealed even among those who only met monthly for the first several months (during the experiment).

To further disentangle these two channels, we exploit experimental variation in meeting frequency at two different points in time. At the time of our lottery, roughly a third of the clients (137 out of 432) were on a subsequent VWS loan cycle in which groups were re-randomized into weekly and monthly meetings (see Appendix Figure 1). VWS has a preference for keeping client groups together across cycles, but group members are replaced when there is drop out. On average, 60% of current group members were also in the first loan group.

We consider the sub-sample of 48 third loan cycle clients who had been on the weekly schedule in the first intervention and examine whether current meeting frequency influences current levels of

³⁰Among this subset of "indirect" lottery winners, 25 were in weekly and 22 were in monthly groups.

³¹The specific question was, "If your friend asked to borrow money or goods from you in the future, do you think you are more, less, or equally likely to share with her than you were before the lottery?" In terms of actual sharing, the most commonly shared goods (post-lottery) were food and sarees. In two cases, winners reported lending money to the group member who had given them the ticket.

cooperation. This allows us to observe whether forcing clients who already know each other well to continue interacting regularly *further* increases cooperation. If so, then it is likely that, in addition to any short-run learning effects that hasten cooperation between members, meeting frequency has persistent benefits via monitoring or discount rate channels.

For this subset of clients, we use pairwise data on ticket-giving to estimate

$$y_{gmi} = \beta_1 W_g^c + \delta_1 \phi_g + \delta_2 D_g + \alpha_g + \epsilon_{gmi} \quad (5)$$

where W_g^c is an indicator variable for the client being on a weekly repayment schedule in the current loan cycle. The other variables are defined as in equations (1) and (2). Given the reduced sample size we report regressions without controls (we observe similar but noisier estimates with controls).

Columns (1) and (2) of Table 6 show that clients in loan groups that were randomly assigned to the weekly schedule in both the first and current loan cycle (“weekly-weekly”) currently see one another significantly more often both at MFI meetings and outside of meetings than clients initially on the weekly schedule but later assigned to the monthly schedule (“weekly-monthly”).³²

Correspondingly, a weekly-weekly client is 29% more likely to engage in pro-social behavior than a weekly-monthly client when the prize is easily divisible (column 3). As before, we find no evidence of increased giving for the indivisible voucher option (column 4). We interpret the difference for weekly-weekly clients in column (3) as evidence that repeated interactions among loan group members helps sustain cooperative arrangements in the long run.

While the period over which learning about other clients can occur is uncertain, it is important to note that, by the time of the survey, clients in this subsample had been interacting regularly for 2.5 loan cycles during which time they saw each other weekly for at least six months and every other week for at least six months more. Consistent with this, we see no difference across weekly-

³²In column (1), the dependent variable is the number of required MFI meetings across the first and current intervention (at the time of the survey). At the time of the lottery, a weekly-monthly client had met, on average, 41 times, while a weekly-weekly client had met roughly 30% more often. Further, the likelihood of a client having group members from the first loan in her current group is independent of repayment frequency (unreported).

weekly and weekly-monthly clients' in the propensity to remember the names of their first loan group members at the time of survey (column 5).

4.4 Social Capital and Default

The above evidence suggests that ticket-giving between clients reflects reciprocal economic ties. Further, the strength of these ties is influenced by group composition and meeting frequency during the lottery client's first loan cycle. Based on these patterns, we can directly estimate the effect of these ties on default risk using an instrumental variables (IV) approach in which random assignment to a weekly group in the first loan cycle *and* having a distant relative or neighbor as a group member is used as an instrument for ticket-giving. The second stage equation is:

$$y_{im} = \gamma_1 t_{im} + \gamma_2 p_{im} + \beta_1 W_g + \delta_1 \phi_g + \delta_2 D_g + \alpha_g + \epsilon_{gmi} \quad (6)$$

where t_{im} is an indicator variable that equals one if either member of the pair gave a ticket and p_{im} is an indicator variable that equals one if the members are either close neighbors or distant relatives. The other variables are as defined in equation (5).

The first stage equation takes the form

$$t_{im} = \rho_1 p_{im} + \rho_2 W_g + \rho_3 p_{im} \times W_g + \rho_4 \phi_g + \rho_5 D_g + \alpha_g + \epsilon_{gmi}. \quad (7)$$

The excluded instrument is the interaction between the weekly indicator (for first loan cycle) and the pair being distant relatives or close neighbors.

The first stage estimates are reported in column (1) of Table 7. Client pairs consisting of distant relatives or close neighbors are 14% more likely to engage in ticket-giving if they were randomly assigned to a weekly group in their first loan cycle. The 2SLS estimates are reported in column (2). The likelihood that at least one member of the pair defaults in the second loan cycle is roughly 50% lower and statistically significant if the pair enjoy reciprocal economic ties, as

evidenced by ticket-giving in the lottery.³³

The validity of the IV estimate depends on the assumption that meeting frequency influenced default rates only through the development of social ties. Since our experiment varied both the frequency of client interaction and the frequency with which they made loan payments and interacted with the loan officer, the central concern is that meeting frequency also influenced clients' financial habits. In that case, simply comparing the behavior of weekly and monthly clients does not allow us to disentangle the effect of social capital from the effect of repayment schedules on default. For instance, repayment frequency could have influenced client income through long-run changes in savings behavior if clients assigned to repay weekly on their first loan developed better savings habits that lasted into subsequent loan cycles.³⁴

For this reason, we do not use assignment to weekly groups as the instrument but rather the differential impact of being in a weekly group for clients of a specific relationship type – those who are reasonably close but not extremely so in terms of geography or familial ties. As there is no obvious reason why the importance of fiscal discipline or, more generally, loan officer indoctrination should depend on this particular group characteristic, the pattern suggests that social capital is the central channel of influence. It is also important to keep in mind that both ticket-giving and default are measured when clients are no longer on their initial repayment schedule. Hence, it is not the case that, at the time of the lottery, clients in the monthly treatment are struggling to make larger payments, which could explain their reluctance to give tickets. Perhaps most importantly, alternative channels of influence such as financial habits cannot account for the fact that ticket-giving within weekly clients is sensitive to voucher divisibility, which was randomly assigned.

³³The results are very similar in magnitude and statistically significant if we estimate these regressions at the client rather than the pair level.

³⁴While possible that income varied across repayment schedules through small interest rate differences (weekly clients faced slightly higher implicit interest rates since they had to repay faster); however, such differences are very small and yield opposite predictions to what we find (weekly clients are more generous and default less).

4.5 The Costs of Building Social Capital

The evidence in Table 7 implies significant benefits to MFIs from building social capital. However, these benefits do not come free given non-trivial transactions costs of meeting four times as often. For clients, we estimate that weekly meetings entail approximately two additional hours per month, or 15 hours over the course of an average loan cycle. Meanwhile, banks could cut transactions costs per client by nearly three-fourths - or reach nearly four times as many clients for the same cost - by moving from a weekly to a monthly schedule.

In terms of benefits default data for the second loan cycle shows that the average client who was on monthly repayment during her initial loan cycle defaults on Rs. 150 more than the average client previously on a weekly repayment schedule, which is almost the same as the bank's additional transaction cost per client of meeting weekly.³⁵ Hence, a conservative back-of-the-envelope calculation suggests that weekly meetings may be cost-effective for a MFI, which explains why MFIs persist with high frequency repayment schedules despite the higher transactions costs.

Evaluating the social planner's problem is less straightforward since the costs and benefits to *clients* of meeting weekly are difficult to calculate. The total cost to clients of regular repayment is likely to exceed the simple time cost of meeting attendance given the additional financial burden of making regular installments, and the total benefits of increases in social capital are likely to exceed the reduction in default risk. While these tradeoffs are difficult to observe, given the wealth of benefits from improved informal insurance and potential externalities from social capital such as information transfers between clients, it is likely that clients are also better off on a weekly schedule.³⁶

³⁵We estimate that loan officers spend an additional 1.5 hours per month per group, which amounts to 3.75% of their monthly wage for every 10 customers, or Rs. 150. Given that a loan cycle is ten months and contains ten members, this implies an average cost per client of roughly Rs. 150.

³⁶While there is one potentially important negative externality that we also do not observe - crowd out of other forms of social capital enjoyed by the client - as argued in Section 3.2, the reduction in client default arguably captures the net effect of meeting frequency on social capital inside and outside of loan groups.

5 Conclusions

A widely held belief across social scientists in many disciplines is that social interactions encourage norms of reciprocity and trust. In fact, participation in groups is often used to measure an individual's or community's degree of economic cooperation (see, for instance, Narayan and Pritchett, 1999; Alesina and Ferrara, 2002). However, while the notion is theoretically well-grounded, it is not clear from previous work whether the correlation between social distance and trust reflects the causal effect of interaction on economic cooperation. Using field experiments, we provide rigorous evidence that repeat interactions can in practice facilitate cooperative behavior by enabling individuals to sustain reciprocal economic ties.

Further, our results demonstrate that development programs can increase social ties and enhance social capital among members of a highly localized community in a strikingly short amount of time. In our study, close neighbors from similar socio-economic backgrounds got to know each other well enough to cooperate with only the outside stimulus of micro-finance meetings. While many authors have suggested a link between social capital and MFI default rates, ours is the first study to provide rigorous evidence on the role of microfinance in building social capital.

Our findings support the idea that complementarities in social capital acquisition creates the possibility of multiple equilibria (Glaeser et al., 2002). This, in turn, suggests potentially large gains from policies which facilitate interaction and help coordinate social capital investments, especially in low income countries where formal risk-sharing arrangements remain limited. By broadening and strengthening social networks the group-based lending model used by MFIs may provide an important impetus for the economic development of poor communities and the empowerment of women. While we cannot expect all communities to respond equally to such stimuli, our findings are likely to be most readily applicable to the fast-growing urban and peri-urban areas of cities in developing countries (such as Kolkata) where microfinance is spreading the most rapidly. Understanding how other development programs or public policies can be designed to enhance the social infrastructure of poor communities is a promising area of future research.

6 Appendix

6.1 VWS Protocol

Group Formation: The loan officer surveys the demographic make-up of a potential neighborhood. If appropriate, then s/he conducts a meeting to inform potential clients about the VWS loan product and invites them to a five-day Continuous Group Training (CGT) program. The program runs an hour each day, and introduces clients to the benefits and responsibilities associated with the loan product. Each potential loan group is assigned a separate CGT program. At the end of the CGT, the loan officer forms women who were considered sufficiently informed and interested into a group, identifies (with group members) a group leader and offers each member of the group a loan.³⁷

Oath The following oath is read out by members in each meeting, “1. We will abide by the rules and regulation of VWS and try to sort out the problems and disturbances in our locality. 2. We

³⁷Group leader selection criteria include: (i) communicates well with group members and VWS staff; (ii) is responsible and well accepted by group members; (iii) has a house or place to organize group meeting.

will send all our children to school. 3. We will maintain good health and keep our houses always neat and clean. 4. We will neither accept nor give any dowry. 5. We will lead a simple life and avoid unnecessary expenses. 6. We will attend the group meeting in time and act as a joint liability group 7. We will use the loan amount for the right purpose.”

6.2 Lottery Protocol

Probability Script for Main Lottery: In the lottery, you and ten other VWS clients will receive a ticket. Additionally, you have the option of selecting additional members of your VWS loan group that you would like us to give tickets to. You can tell us not to give anybody else in your VWS loan group a ticket, you can tell us to give each person in your group a ticket, or you can tell us which specific members you would like us to give tickets to.

We will review the effect giving out tickets has on chances of winning. In picture 1 in which you donot give out any tickets to members of your VWS group, you would have a 1 in 11 chance of winning. In picture 2, you choose to give a ticket to four other members of your VWS group and there are 15 tickets total. In that case, you would have a 1 in 15 chance of winning and each of the members of your VWS group you gave a ticket to would have a 1 in 15 chance of winning. In picture 3, you give a ticket to nine other members of your VWS group and there are 20 tickets total. In that case, you would have a 1 in 20 chance of winning and each of the members of your VWS group you gave a ticket to would have a 1 in 20 chance of winning.

These are only a few examples of what odds of winning you may have after you decide how many tickets to give out. Remember that whether or not you give out tickets to other members of your first VWS loan group, you keep the lottery ticket we have given you. Now, before we continue, do you have any questions about how the lottery will work?

Additional Script for one 200 Rs. voucher: If you win the lottery, you will receive a single 200 Rs. voucher redeemable at the VWS village bazaar. You can use the voucher yourself or give it to someone in your first VWS group. Either way, the voucher must be used within two weeks.

Additionally, only one person can redeem the voucher at the VWS store and the entire value of the voucher must be used when the voucher is redeemed (so, for example, you cannot use 100 Rs. one day and save 100 Rs. for another day). To summarize, if you win the lottery, you will be asked to sign the 200 Rs. voucher when you receive it. However, you are still free to decide whether to keep or give away the voucher that you receive.

Additional Script for four 50 Rs. vouchers: If you win the lottery, you will receive four 50 Rs. vouchers redeemable at the VWS village bazaar. You may choose to use all four vouchers yourself, to give away 1-3 of the vouchers to members of your first VWS group and keep the rest for yourself, or to give away all of the vouchers to members of your first VWS group. In any case, the vouchers must be used within two weeks. Additionally, the entire value of each of the vouchers must be used when the voucher is redeemed (so, for example, you cannot use 25 Rs. of a 50 Rs. voucher one day and save 25 Rs. for another day). To summarize, if you win the lottery, you will be asked to sign each of the 50 Rs. vouchers when you receive them. However, you are still free to decide whether to give away or keep each of the four vouchers that you receive.

6.3 Sample and Loan Terms

Our experimental sample consisted of 1026 clients who each received a Rs. 4000 loan and were randomized into either a weekly or monthly group. Of these, 707 chose to take out a second loan within 104 weeks of having taken out the first loan. 458 were on a fortnightly repayment schedule without an initial delay, and 249 were on a fortnightly repayment schedule with a two month delay before the first loan repayment was due. Of these, 137 took out a third loan where they were re-randomized into monthly or weekly loans. Of these, 48 clients had been on a weekly schedule in their first loan cycle and these clients enter the sample in Table 6. For these clients, the average loan size in the third loan cycle was Rs. 9600.

We piloted the lottery among 128 clients and then randomly drew a sample of 450 clients from the remaining 900. Of these, two had died and sixteen were away from the city.

Table 1. Group-level and Client-level Randomization Check

	Summary Statistics- All Clients		Weekly/Monthly Difference

N	306	710	1016	428	219	209

Notes

¹ Month of Formation refers to calendar month of group formation ("4" for groups formed in April, 2006, and so on). Impatient is whether client prefers "Rs. 200 now" over "Rs. 250 in one month." Close Neighbors are neighbors living within 50m. The omitted relationship type is Close Family/Friends, and all relationship types are defined at time of loan group formation. Financial Control is whether clients responds "Yes" to "If a close relative like your parents or siblings fell sick and needed money would you be able to lend money to that relative, if you had the extra money?"

² Columns (3)-(6) report tests of differences of means (weekly minus monthly) for the subsamples. Standard errors are clustered by group.

Table 2. Meeting Frequency and Social Contact/ Trust Measures

	Social Contact					Trust Measures	
	Short Run Index	Long Run Index		Total Times Met		Trust Group Members	Would Help if Sick
	(1)	(2)	(3)	(4)	(5)	(6)	(7)

Mean of Monthly				4.462		4.320	0.226
N	100	3134	3134	[9.728] 3134	3134	[1.132] 432	[0.418] 4018

Notes:

- 1 Short Run Index averages the normalized group mean of four client indicator variables: "Have all of your group members visited your house?", "Have you ever visited houses of all group members?", "Do you know the names of the family members of your group members?", and "Do you know if any of your group members had relatives come over in last 30 days?" Long Run Index averages three (normalized) client-level variables: Total Times Met (reference period past 30 days), (2) "Do you still talk to X about her family," and (3) "During the most recent Durga Puja, did you attend any part of the festival with X?" Trust Group Member is the client response on a 1 to 5 scale, increasing in the likelihood that the average group member would return a wallet with Rs. 200 that was found on the street. Would Help if Sick is the indicator variable "If you had a sick family member and had to leave your house for a few hours for an emergency, would you ask X to come to your home and look after him/her?"
- 2 Distant Relative, Close Neighbor, Distant Neighbor, and Didn't Know are responses to pairwise relationship type before joining VWS. The omitted group is close family/friends.
- 3 Mean of monthly is average of the dependent variable for monthly groups/clients, standard deviations in brackets.
- 4 In Columns (2)-(5) we include one response per loan group pair. Column (1) regression includes group-level controls (Table 1, Panel A). Columns (2)-(7) regressions control, in addition, for client controls (Table 1, Panel B), days between loan disbursement and lottery survey, and whether member is group leader. Standard errors are clustered by group in Columns (2)-(7).

Table 3. Meeting Frequency and Loan Repayment

	Transfers		Default		
	Neighbor/ Other Relative/ Friend	Close Family/ Other Non-Relative	First Loan	Second Loan	
	(1)	(2)		(4)	(5)

Fraction Distant Relatives or Close Neighbors in Group					0.137 (0.116)
Weekly*Fraction Distant Relatives or Close Neighbors in Group					-0.186 (0.099)
Mean of monthly	0.377 [0.485]	0.377 [0.485]	0.018 [0.133]	0.108 [0.301]	
N	961	961	1026	707	707

Notes:

- 1 Transfers in Columns (1)-(2) refer to transfers given/received by clients' household in 12 months before first loan endline survey, and are indicator variables for whether clients' household gave/received any transfers to/from the relevant groups. Relationship type is defined at end of loan cycle for transfers, but is defined before joining VWS for default regression. For each loan, a client is defined as defaulted if she has not repaid the total loan amount within forty-four weeks after due date. Data on loan repayment was still collected weekly after the end of the loan cycle.
- 2 Regressions include loan officer fixed effects (for that cycle). All regressions include controls for the variables in Table 1. Standard errors are clustered at the group-level.

Table 4. Determinants of Ticket Giving

	Gave Ticket	
	(1)	(2)

Distant Neighbor		-0.281 (0.024)
Didn't Know		-0.398 (0.024)
N	4018	4018

Notes

- ¹ We have (on average) nine observations per client. The dependent variable equals one for a group member if the client gave her a ticket. Time Spent on Political Activity/ Community Meetings is the indicator variable "Did you spend any time on political activities / attending community meetings in the last 24 hours?"
- ² All regressions include controls for days between loan disbursement and lottery survey, group size, and month of group formation fixed effects.

N	2027	2027	2027	2027	1991	1991	1991	1991

Notes

- 1 For each client in the sample we have (on average) nine observations. See notes to Table 4 for definition of dependent variable, and notes to Table 1 for Impatient, Financial Control, and relationship type definitions.
- 2 Regressions include (i) a control for days between loan disbursement and lottery survey, and (ii) controls for the variables in Table 1, Panels A-B. Regressions also include controls for loan group leader. Standard errors are clustered at the group-level.

Table 6. Meeting Frequency across Loan Cycles and Pro-Social Behavior

	Number of Pre-Lottery MFI Meetings Attended	Current Social Contact Index	Gave Ticket		Member Remember
			4-Rs. 50. Vouchers	1-Rs. 200 Voucher

	(2.455)	(0.505)	(0.099)	(0.175)	(0.095)
Mean of Weekly in First Loan, Monthly in Current Loan	41.388		0.126	0.281	0.669
	[4.220]		[0.333]	[0.451]	[0.472]
Specification	Client-level	Client-level	Pairwise	Pairwise	Pairwise
N	48	47	251	204	455

Notes

- 1 The sample is weekly clients with a VWS loan at the time of lottery. Number of Pre-Lottery MFI Meetings is the total number of times the client's First Loan and Current Loan group met to repay before the client was surveyed for lottery. Social Contact Index is the average of the normalized versions of five Current Loan group meeting variables: "For how many members of your group do you know whether there is a marriage ceremony in the family in the coming 30 days?", "How many group members have you visited in their houses in the last 2 weeks?", "How many group members have visited you in your house in the last 2 weeks?", "How many people in the group did you talk to about business matters in the last 2 weeks?", and "How many people in the group did you talk to about personal matters in the last 2 weeks?" For each variable, we use client-level average across all observations before month 4 of the current loan cycle (when the average client was surveyed for the lottery). Gave Ticket is as defined in notes to Table 4. Member Remember is the indicator variable "Do you remember this group member?" Data in Columns (1)-(2), was collected over the course of Current Loan Cycle, while data in Columns (3)-(5) was collected at the time of lottery.
- 2 Regressions include month of First and Current Loan group formation fixed effects. Standard errors are clustered at the First Loan group-level.

Table 7. Meeting Frequency and Loan Repayment

	Gave Ticket	Second Loan Default- IV (Pairwise)
	(1)	(2)
Weekly	0.006 (0.051)	-0.070 (0.057)
Distant Relative or Close Neighbor	-0.075 (0.048)	-0.020 (0.046)
Weekly*Distant Relative or Close Neighbor	0.143 (0.053)	
Gave Ticket		-0.478 (0.178)
N	2007	2007

Notes

- ¹ We report an IV result in Column (2) in which we instrument for Gave Ticket with Weekly*Distant Relative or Close Neighbor. The first stage of the IV is given in Column (1). The dependent variable in Column (2) is an indicator variable for whether either sender or receiver defaulted.
- ² All regressions include controls for the variables in Table 1, Panels A-B and for loan group leader. Regressions also include controls for second loan officer and second loan month of loan disbursement. Standard errors are clustered at both the first and second loan group level.

Fixed Salary Earned by Household	1460 [2998]	1560 [2602]	-100 (251)	25 (331)	114 (385)	-68 (471)
Fraction of Clients Surveyed				-0.009 (0.038)		
N	306	710				

Notes

- ¹ Illness in Past 12 Months is an indicator variable for whether any household member has been ill in past 12 months. Total Transfers into/ out of Household is defined for households which made/received at least one transfer over past 12 months. Columns (3)-(6) report tests of differences of means for the different subsamples. Standard errors are clustered by group. Fraction of clients surveyed is the group-level fraction of clients receiving lottery survey.

Appendix Table 2. Meeting Frequency and Social Interaction

	Short Run				Long Run		
	All Members Visited Me in My Home	I Visited All Members in Their Homes	Know Names of Family Members	Know if Relatives Visited	Total Times Met	Talk Family	Attend Durga Puja Together
	(1)	(2)	(3)	(4)	(5)	(6)	(7)
Weekly	0.947 (0.036)	0.940 (0.036)	0.945 (0.036)	0.103 (0.013)	0.829 (0.601)	0.060 (0.026)	0.071 (0.038)
Mean of	0.101	0.105	0.100	0.003	4.463	0.183	0.166
Monthly	[0.246]	[0.246]	[0.244]	[0.015]	[9.732]	[0.387]	[0.372]
N	100	100	100	100	3134	4018	4018

Notes:

- 1 Dependent variables in Columns (1)-(7) are as defined in Table 2.
- 2 Mean of monthly is average value of dependent variable for monthly clients with standard deviations in brackets.
- 3 Columns (1)-(4) regressions include group-level controls (Table 1, panel A). Columns (5)-(7) regressions control, in addition, for client-level controls (Table 1, Panel B), days between loan disbursement and lottery survey, and whether member is group leader.

Figure 1. Building Social Capital over the Loan Cycle

Figure 2. Transfers Given by Weekly/Monthly Clients

Notes:

Relationship categories are based on responses to the endline survey, and so differ from the categories based on lottery survey responses. Here, Neighbor/Other Relative includes the two categories: "Neighbor" and "Other Relative". Other Non-Relative simply refers to the category of that name, Friend includes "Friend" and "VWS Group Member", and Close Family includes all other relationship types.

Figure 3. Winning Probabilities

Notes:

This picture was used to explain how ticket-giving affected lottery probabilities. The explanation provided was "In Picture 1 in which you don't give out any tickets to members of your VWS group, you have a 1 in 11 chance of winning.

In Picture 2, you choose to have us give a ticket to four other members of your VWS group and there are 15 tickets total. In that case, you would have a 1 in 15 chance of winning and each of the members of your VWS group you gave a ticket to would have a 1 in 15 chance of winning.

In Picture 3, you choose to have us give a ticket to nine other members of your VWS group and there are 20 tickets total. In that case, you would have a 1 in 20 chance of winning and each of the members of your VWS group you gave a ticket to would have a 1 in 20 chance of winning."

Figure 5. Network Structures

Panel A: Weekly Clients

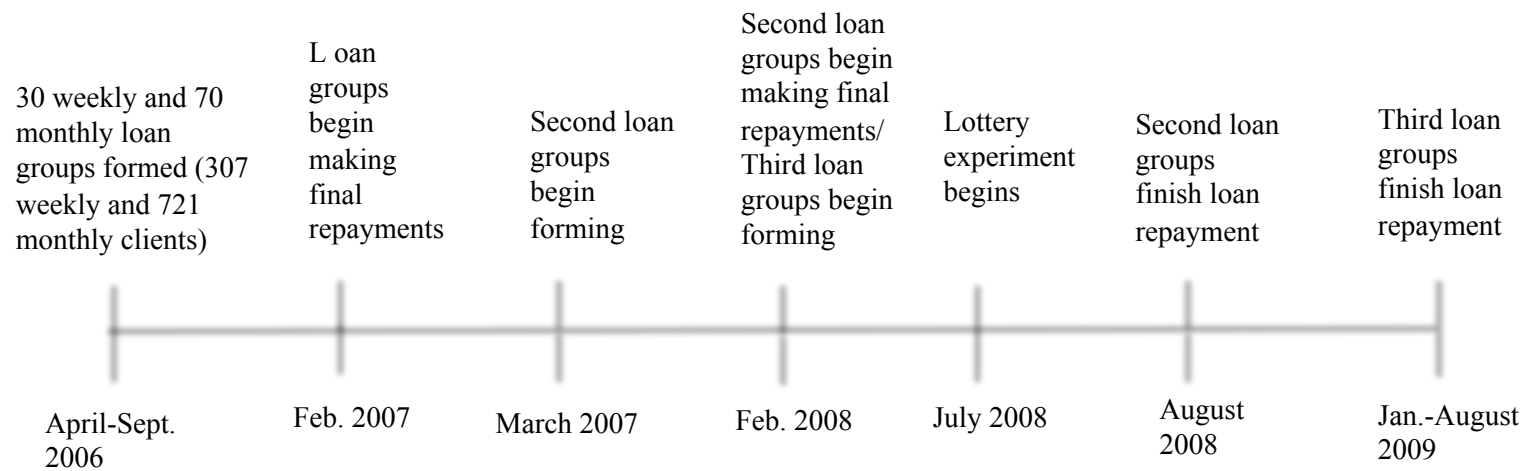

Panel B: Monthly Clients

Circular nodes are clients from the 4-Rs. 50 gift voucher randomization, square nodes are clients from the 1-Rs. 200 gift voucher randomization, and triangular nodes are clients who were not surveyed for the lottery. Nodes are labelled by the number of tickets given out by client, and edges depict direction of ticket-giving.

Appendix Figure 1. Timeline

Appendix Figure 2. Expected Returns to Lottery by Ticket-Giving Decision

Notes:

Appendix Figure 2 shows the expected returns to the lottery based on ticket-giving decision, and extent of reciprocal behavior by ticket recipient.

Appendix Figure 3. Lottery Vouchers

VILLAGE WELFARE SOCIETY VILLAGE MICRO CREDIT SERVICES
TOGETHER TOWARDS PROSPERITY

Rs. 50 Voucher
Single Use Only

Whoever reclaims this voucher must bring their VWS passbook with them to the VWS village bazaar when making their purchase. If the claimant is no longer a VWS client, they should bring their voter identification card.

Date of Lottery: _____	Deadline to Claim: _____
Group Name: _____	Name of Claimant: _____
Name of Winner: _____	Signature of Claimant: _____
Signature of Winner: _____	

VILLAGE WELFARE SOCIETY VILLAGE MICRO CREDIT SERVICES
TOGETHER TOWARDS PROSPERITY

RS. 200 VOUCHER
Single Use Only

Whoever reclaims this voucher must bring their VWS passbook with them to the VWS village bazaar when making their purchase. If the claimant is no longer a VWS client, they should bring their voter identification card.

Date of Lottery: _____	Deadline to Claim: _____
Group Name: _____	Name of Claimant: _____
Name of Winner: _____	Signature of Claimant: _____
Signature of Winner: _____	

Note:

Clients were randomly offered the choice of joining the 1-Rs. 200.Voucher or the 4-Rs. 50 Voucher lottery. This figure shows the final vouchers which were given to the winner of the two lotteries.
